Lecture 15: Course Summary

L1-L5 Specifications, models and loop-shaping by hand

L6-L8 Limitations on achievable performance

L9-L11 Controller optimization: Analytic approach

L12-L14 Controller optimization: Numerical approach

Examples

Flexible servo resonant system

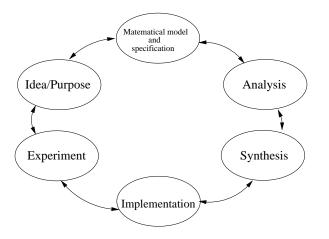

Quadruple tank system multivariable (MIMO), NMP-zero

Rotating crane multivariable, observer needed

DVD control resonant system, wide frequency range, (midranging)

Bicycle steering unstable pole/zero-pair

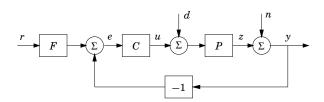

Distillation column MIMO, input-output pairing

Course Summary

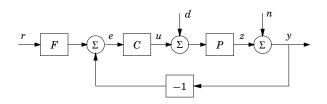

- Specifications, models and loop-shaping
- o Limitations on achievable performance
- O Controller optimization: Analytic approach
- O Controller optimization: Numerical approach

2DOF control

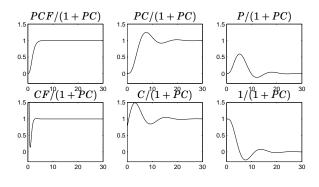

- ► Reduce the effects of load disturbances
- ▶ Limit the effects of measurement noise
- Reduce sensitivity to process variations
- ► Make output follow command signals

2DOF control

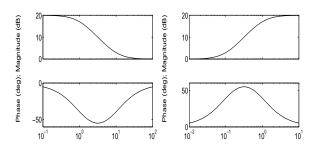

$$\begin{split} U &= -\frac{PC}{1+PC}D - \frac{C}{1+PC}N + \frac{CF}{1+PC}R \\ Y &= \frac{P}{1+PC}D + \frac{1}{1+PC}N + \frac{PCF}{1+PC}R \end{split}$$

Important Step Responses

Lag and lead filters for loop-shaping of P(s)C(s)

$$C(s) = \frac{s+10}{s+1}$$
 $C(s) = \frac{10(s+1)}{(s+10)}$

MIMO-systems

If C,P and F are general MIMO-systems, so called $\it transfer$ function $\it matrices$, the $\it order$ of $\it multiplication$ $\it matters$ and

$$PC \neq CP$$

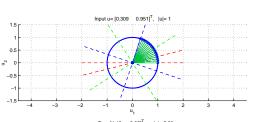

and thus we need to multiply with the inverse from the correct side as in general

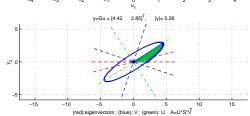

$$(I+L)^{-1}M \neq M(I+L)^{-1}$$

Note, however that

$$(I + PC)^{-1}PC = P(I + CP)^{-1}C = PC(I + PC)^{-1}$$

Different gains in different directions: $\begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} 2 \\ 0 \end{bmatrix}$

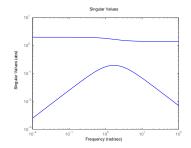

Plot Singular Values of $G(i\omega)$ Versus Frequency

- » s=tf('s')
- » G=[1/(s+1) 1; 2/(s+2) 1]
- » sigma(G) % plot singular values

% Alt. for a certain frequency:

- w = 1;
- » A = [1/(i*w+1) 1; 2/(i*w+2) 1]
- V [U,S,V] = svd(A)

Realization of Multi-variable system

Example: To find state space realization for the system

$$G(s) = \begin{bmatrix} \frac{1}{s+1} & \frac{2}{(s+1)(s+3)} \\ \frac{6}{(s+2)(s+4)} & \frac{1}{s+2} \end{bmatrix}$$

write the transfer matrix as

$$\left[\frac{\frac{1}{s+1}}{\frac{3}{s+2}-\frac{3}{s+4}} \quad \frac{\frac{1}{s+1}-\frac{1}{s+3}}{\frac{1}{s+2}}\right] = \frac{\left[\frac{1}{0}\right]\left[1 \quad 1\right]}{s+1} + \frac{\left[0\right]\left[3 \quad 1\right]}{s+2} - \frac{\left[\frac{1}{0}\right]\left[0 \quad 1\right]}{s+3} - \frac{\left[0\right]\left[3 \quad 0\right]}{s+4}$$

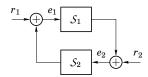

This gives the realization

$$\begin{bmatrix} \dot{x}_1(t) \\ \dot{x}_2(t) \\ \dot{x}_3(t) \\ \dot{x}_4(t) \end{bmatrix} = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & -2 & 0 & 0 \\ 0 & 0 & -3 & 0 \\ 0 & 0 & 0 & -4 \end{bmatrix} \begin{bmatrix} x_1(t) \\ x_2(t) \\ x_3(t) \\ x_4(t) \end{bmatrix} + \begin{bmatrix} 1 & 1 \\ 3 & 1 \\ 0 & -1 \\ -3 & 0 \end{bmatrix} \begin{bmatrix} u_1(t) \\ u_2(t) \end{bmatrix} \\ \begin{bmatrix} y_1(t) \\ y_2(t) \end{bmatrix} = \begin{bmatrix} 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \end{bmatrix} x(t)$$

The Small Gain Theorem

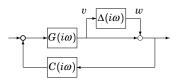

Consider a system $\mathcal S$ with input u and output $\mathcal S(u)$ having a (Hurwitz) stable transfer function G(s). Then, the system gain

$$\|\mathcal{S}\| := \sup_{u} \frac{\|\mathcal{S}(u)\|}{\|u\|} \quad \text{ is equal to } \quad \|G\|_{\infty} := \sup_{\omega} |G(i\omega)|$$

Assume that \mathcal{S}_1 and \mathcal{S}_2 are input-output stable. If $\|\mathcal{S}_1\| \cdot \|\mathcal{S}_2\| < 1$, then the gain from (r_1, r_2) to (e_1, e_2) in the closed loop system is finite

Application to robustness analysis

The transfer function from w to v is

$$\frac{G(i\omega)C(i\omega)}{1+G(i\omega)C(i\omega)}$$

Hence the small gain theorem guarantees closed loop stability for all perturbations $\boldsymbol{\Delta}$ with

$$\|\Delta\| < \left(\sup_{\omega} \left| \frac{G(i\omega)C(i\omega)}{1 + G(i\omega)C(i\omega)} \right| \right)^{-1}$$

Course Summary

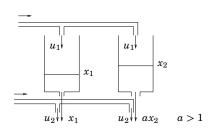

O Specifications, models and loop-shaping

• Limitations on achievable performance

- O Controller optimization: Analytic approach
- O Controller optimization: Numerical approach

Example: Two water tanks

Example from Lecture 6:

$$\dot{x}_1 = -x_1 + u_1$$

$$\dot{x}_2 = -ax_2 + u_1$$

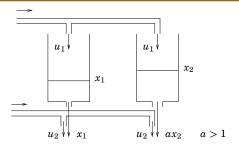

$$y_1 = x_1 + u_2$$

$$y_2 = ax_2 + u_2$$

Can you reach $y_1 = 1, y_2 = 2$?

Can you stay there?

Example: Two water tanks

$$\dot{x}_1 = -x_1 + u_1$$

$$\dot{x}_2 = -ax_2 + u_1$$

The controllability Gramian $S=\int_0^\infty \begin{bmatrix} e^{-t}\\ e^{-at}\end{bmatrix} \begin{bmatrix} e^{-t}\\ e^{-at}\end{bmatrix}^T dt = \begin{bmatrix} \frac{1}{2} & \frac{1}{a+1}\\ \frac{1}{a+1} & \frac{1}{2a} \end{bmatrix}$

is close to singular for $a \approx 1$, so it is harder to reach a desired state.

$AS + SA^T + BB^T = 0$

Computing the controllability Gramian

The controllability Gramian $S=\int_0^\infty e^{At}BB^Te^{A^Tt}dt$ can be computed

 $S=S^T>0$, i.e., S is a symmetric positive definite matrix

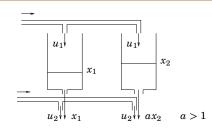

by solving the linear system of equations

Assign

$$S = \begin{bmatrix} s_{11} & s_{12} \\ s_{12} & s_{22} \end{bmatrix}$$

Multiply together and solve for $s_{11},\,s_{12},\,s_{22}$ in the same way as you also do for the spectral factorization and the Riccati equations...

Example: Two water tanks

$$\dot{x}_1 = -x_1 + u_1$$

$$\dot{x}_2 = -ax_2 + u_1$$

$$G(s) = egin{bmatrix} rac{1}{s+1} & 1 \ rac{2}{s+2} & 1 \end{bmatrix}$$
 . Find zero from $\det G(s) = rac{-s}{(s+1)(s+2)}$

There is a zero at s=0! Outputs must be equal at stationarity.

Sensitivity bounds from RHP zeros and poles

Rules of thumb:

"The closed-loop bandwidth must be less than z."

"The closed-loop bandwidth must be greater than p."

"Time delays T must be less than 1/p."

Hard bounds:

The sensitivity must be one at an unstable zero:

$$P(z) = 0$$
 \Rightarrow $S(z) := \frac{1}{1 + P(z)C(z)} = 1$

The complimentary sensitivity must be one at an unstable pole:

$$P(p) = \infty$$
 \Rightarrow $T(p) := \frac{P(p)C(p)}{1 + P(p)C(p)} = 1$

Maximum Modulus Theorem

Assume that G(s) is rational, proper and stable. Then

$$\max_{\operatorname{Re} s \geq 0} |G(s)| = \max_{\omega \in \mathbf{R}} |G(i\omega)|$$

Corollary:

Suppose that the plant P(s) has unstable zeros z_i and unstable poles p_j . Then the specifications

$$\sup_{\omega} |W_a(i\omega)S(i\omega)| < 1 \qquad \sup_{\omega} \left|W^b(i\omega)T(i\omega)
ight| < 1$$

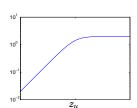

are impossible to meet with a stabilizing controller unless $\|W_a(z_i)\| < 1$ for every unstable zero z_i and $\|W^b(p_j)\| < 1$ for every unstable pole p_j .

Hard limitations from unstable zeros

If the plant has an unstable zero z_u , then the specification

$$\left|\frac{1}{1+P(i\omega)C(i\omega)}\right|<\frac{2}{\sqrt{1+z_u^2/\omega^2}} \qquad \qquad \text{for all } \alpha$$

is impossible to satisfy.

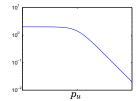

Examples: Rear-wheel steering and quadruple tank process

Hard limitations from unstable poles

If the plant has an unstable pole p_u , then the specification

$$\left|\frac{P(i\omega)C(i\omega)}{1+P(i\omega)C(i\omega)}\right|<\frac{2}{\sqrt{\omega^2/p_u^2+1}} \qquad \quad \text{for all } \omega$$

is impossible to satisfy.

Example: Inverted pendulum

Nonmin-phase zero and unstable pole

Let $P = \widehat{P}(s-z)(s-p)^{-1}$, with \widehat{P} proper and $\widehat{P}(p) \neq 0$.

Then, for stable closed loop the sensitivity function satisfies

$$\sup_{\omega} |S(i\omega)| \ge \left| \frac{z+p}{z-p} \right|$$

so if $p \approx z$, then the sensitivity function must have a high peak for every controller C.

Example: Bicycle with rear wheel steering

$$\frac{\theta(s)}{\delta(s)} = \frac{am\ell V_0}{bJ} \cdot \frac{\left(-s + V_0/a\right)}{\left(s^2 - mg\ell/J\right)}$$

Relative Gain Array (RGA)

For a square matrix $A \in {\mathbf C}^{n imes n}$, define

$$RGA(A) := A. * (A^{-1})^T$$

where ".*" denotes element-by-element multiplication. (For a non-square matrix, use pseudo inverse A^\dagger)

- ▶ The sum of all elements in a column or row is one.
- ightharpoonup Permutations of rows or columns in A give the same permutations in ${\rm RGA}(A)$
- ightharpoonup RGA(A)=RGA (D_1AD_2) if D_1 and D_2 are diagonal, i.e. RGA(A) is independent of scaling
- ▶ If *A* is triangular, then RGA(*A*) is the unit matrix *I*.

RGA for a Distillation Column

- Find a permutation of inputs and outputs that makes ${\sf RGA}(P(0))$ as close as possible to the identity matrix.
- ightharpoonup Avoid pairings that give negative diagonal elements of $\mathsf{RGA}(P(0))$

$$\mathsf{RGA}(P(0)) = \begin{bmatrix} 0.2827 & -0.6111 & 1.3285 \\ 0.0134 & 1.5827 & -0.5962 \end{bmatrix}$$

To choose control signal for y_1 , we apply the heuristics to the top row and choose u_3 . Based on the bottom row, we choose u_2 to control y_2 . Decentralized control!

Decoupling

Simple idea: Find a compensator so that the system appears to be without coupling ("block-diagonal transfer function matrix").

- ▶ Input decoupling $Q = PD_1$
- ▶ Output decoupling $Q = D_2 P$
- "both" $Q = D_2 P D_1$

Find D_1 and D_2 so that the controller sees a "diagonal plant":

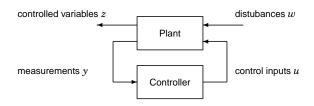

$$D_2PD_1 = \begin{bmatrix} * & 0 & 0 \\ 0 & * & 0 \\ 0 & 0 & * \end{bmatrix}$$

Then we can use a "decentralized" controller ${\cal C}$ with same block-diagonal structure.

Course Summary

- Specifications, models and loop-shaping
- Limitations on achievable performance
- Controller optimization: Analytic approach
- Controller optimization: Numerical approach

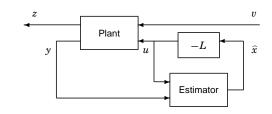

A General Optimization Setup

The objective is to find a controller that optimizes the transfer matrix $G_{zw}(s)$ from disturbances w to controlled outputs z.

Lecture 9-11: Problems with analytic solutions Lectures 12-14: Problems with numeric solutions

Output feedback using state estimates

Plant:
$$\begin{cases} \dot{x}(t) = Ax(t) + Bu(t) + v_1(t) \\ y(t) = Cx(t) + v_2(t) \end{cases}$$

$$\text{Controller:} \quad \begin{cases} \frac{d}{dt} \hat{x}(t) = A \hat{x}(t) + B u(t) + K[y(t) - C \hat{x}(t)] \\ u(t) = -L \hat{x}(t) \end{cases}$$

Linear Quadratic Optimal Control (LQG)

Given the linear plant

$$\begin{cases} \dot{x}(t) = Ax(t) + Bu(t) + v_1(k) & Q = \begin{bmatrix} Q_1 & Q_{12} \\ Q_{12}^T & Q_2 \end{bmatrix} \\ y(t) = Cx(t) + v_2(t) & R = \begin{bmatrix} R_1 & R_{12} \\ R_{12}^T & R_2 \end{bmatrix} \end{cases}$$

consider controllers of the form $u=-L\widehat{x}$ with $\frac{d}{dt}\widehat{x}=A\widehat{x}+Bu+K[y-C\widehat{x}].$ The frequency integral

trace
$$rac{1}{2\pi}\int_{-\infty}^{\infty}QG_{zv}(i\omega)RG_{zv}(i\omega)^*d\omega$$

is minimized when \boldsymbol{K} and \boldsymbol{L} satisfy

$$\begin{split} 0 &= Q_1 + A^TS + SA - (SB + Q_{12})Q_2^{-1}(SB + Q_{12})^T & L &= Q_2^{-1}(SB + Q_{12})^T \\ 0 &= R_1 + AP + PA^T - (PC^T + R_{12})R_2^{-1}(PC^T + R_{12})^T & K &= (PC^T + R_{12})R_2^{-1} \end{split}$$

The minimal value of the integral is

$$\operatorname{tr}(SR_1) + \operatorname{tr}[PL^T(B^TSB + Q_2)L]$$

Stochastic Interpretation of LQG Control

Given white noise (v_1,v_2) with intensity R and the linear plant

$$\begin{cases} \dot{x}(t) = Ax(t) + Bu(t) + v_1(t) \\ y(t) = Cx(t) + v_2(t) \end{cases} \qquad R = \begin{bmatrix} R_1 & R_{12} \\ R_{12}^T & R_2 \end{bmatrix}$$

consider controllers of the form $u=-L\widehat{x}$ with $\frac{d}{dt}\widehat{x}=A\widehat{x}+Bu+K[y-C\widehat{x}].$ The stationary variance

$$\mathbf{E}\left(x^TQ_1x + 2x^TQ_{12}u + u^TQ_2u\right)$$

is minimized when K and L satisfy

$$\begin{split} 0 &= Q_1 + A^T S + S A - (SB + Q_{12}) Q_2^{-1} (SB + Q_{12})^T & L &= Q_2^{-1} (SB + Q_{12})^T \\ 0 &= R_1 + AP + P A^T - (PC^T + R_{12}) R_2^{-1} (PC^T + R_{12})^T & K &= (PC^T + R_{12}) R_2^{-1} \end{split}$$

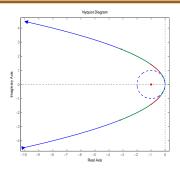

The minimal variance is

$$\operatorname{tr}(SR_1) + \operatorname{tr}[PL^T(B^TSB + Q_2)L]$$

Course Summary

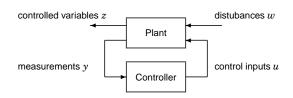

- O Specifications, models and loop-shaping
- Limitations on achievable performance
- O Controller optimization: Analytic approach
- Controller optimization: Numerical approach

Stability robustness of optimal state feedback

Notice that the distance from $L(i\omega I-A)^{-1}B$ to -1 is never smaller than 1. This is always true (!) for linear quadratic optimal state feedback when $Q_1>0$, $Q_{12}=0$ and $Q_2=\rho>0$ is scalar. Hence the phase margin is at least 60° .

The Q-parametrization (Youla)

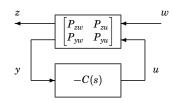

Idea for lecture 12-14:

The choice of controller generally corresponds to finding Q(s), to get desirable properties of the map from w to z:

Once Q(s) is determined, a corresponding controller is derived.

The Youla Parametrization

The closed loop transfer matrix from \boldsymbol{w} to \boldsymbol{z} is

$$G_{zw}(s) = P_{zw}(s) - P_{zu}(s)Q(s)P_{yw}(s)$$

where

$$Q(s) = C(s) [I + P_{vu}(s)C(s)]^{-1}$$

$$C(s) = Q(s) + Q(s)P_{yu}(s)C(s)$$

$$C(s) = \left[I - Q(s)P_{yu}(s)\right]^{-1}Q(s)$$

Synthesis by convex optimization

A general control synthesis problem can be stated as a convex optimization problem in the variables Q_0,\dots,Q_m . The problem has a quadratic objective, with linear and quadratic constraints:

Once the variables Q_0,\dots,Q_m have been optimized, the controller is obtained as $C(s)=[I-Q(s)P_{yu}(s)]^{-1}Q(s)$

Model reduction by balanced truncation

Consider a balanced realization

$$\begin{bmatrix} \dot{\xi}_1 \\ \dot{\xi}_2 \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \begin{bmatrix} \xi_1 \\ \xi_2 \end{bmatrix} + \begin{bmatrix} B_1 \\ B_2 \end{bmatrix} u \qquad \Sigma = \begin{bmatrix} \Sigma_1 & 0 \\ 0 & \Sigma_2 \end{bmatrix}$$

$$y = \begin{bmatrix} C_1 & C_2 \end{bmatrix} \begin{bmatrix} \xi_1 \\ \xi_2 \end{bmatrix} + Du$$

$$\begin{bmatrix} \sigma_{r+1} & 0 \end{bmatrix}$$

with the lower part of the gramian being $\Sigma_2 = \begin{bmatrix} \sigma_{r+1} & 0 \\ & \ddots \\ 0 & \sigma_n \end{bmatrix}$

Replacing the second state equation by $\dot{\xi}_2=0$ gives the relation $0=A_{21}\xi_1+A_{22}\xi_2+B_2u$. The reduced system

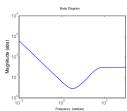

$$\begin{cases} \dot{\xi}_1 = (A_{11} - A_{12}A_{22}^{-1}A_{21})\xi_1 + (B_1 - A_{12}A_{22}^{-1}B_2)u \\ y_r = (C_1 - C_2A_{22}^{-1}A_{21})\xi_1 + (D - C_2A_{22}^{-1}B_2)u \end{cases}$$

satisfies the error bound

$$\frac{\|y - y_r\|_2}{\|u\|_2} \le 2\sigma_{r+1} + \dots + 2\sigma_n$$

DC-servo example

Recall the Bode plot of the optimized controller $C_{
m opt}(s)$ from Lec.14:

The Hankel singular values of $C_{\mathsf{stab}}(s) = C_{\mathsf{opt}}(s) + \frac{6.17}{s}$ are

Only one state needs to be kept in $C_{\mathrm{stab}}(s)$.

What remains of $C_{\mathrm{opt}}(s) = C_{\mathrm{stab}}(s) - \frac{6.17}{s}$ is a PID controller.
